ABSTRACT

Two specific applications for networks might be used to serve the biomedical community: (1) networking of the nation's educational television (ETV) stations for occasional or one-time broadcasting and (2) networking of the nation's medical schools for continuous broadcasting. These two applications are analyzed in detail. A second contribution of this analysis is the provision of data and methodology for examining costs and effectiveness (in terms of physicians and students within broadcasting range) of configurations of subsets of points in the full network. The data and methodology could also be used for determining the minimum cost for networks using media other than broadband television broadcasting, such as audio only broadcasting in conjunction with slides or still pictures. The cost attractiveness of networked, simultaneous broadcasting can also be compared with, for example, sequential broadcasting using mailed video tapes. (NH)

PREFACE

The Lister Hill National Center for Biomedical Communications of the National Library of Medicine (NLM) has been appointed by the Board of Regents of the NLM to assume the responsibility for the development of, and the coordinated planning for, Biomedical Communications. At the request of the Center, Rand has undertaken the examination of broadband telecommunication systems in biomedical communications. This Memorandum documents the initial analysis of one application of this mode of communication utilizing common carrier land lines for networking. It is part of Rand's effort for the Center in the analysis of various applications of technology to the needs of biomedical information dissemination.

/v/ -v-

SUMMARY

This Memorandum deals with the problem of estimating the cost of networking the TV broadcasting of biomedical information, using common carrier land lines. Such networking costs are made up of three components: interexchange channel costs based on the intercity distances between broadcast points and the number of hours of broadcasting; a station connection charge for a switching connection between the broadcast point and the local common carrier facility, which includes both a fixed charge and a charge based on the number of hours of use; and local channel charges for connecting the broadcast point and the local facility.

To estimate the costs efficiently, using these charge rates, it was necessary to calculate minimum distance networks for connecting the points in each network. Such a network is generally known as a "minimal weighted spanning tree." In this case, the weights are the distances between broadcast points. The algorithm for these calculations was programmed for computers and provides the basic framework for the cost estimates.

Two major networking applications were considered: the networking on a national basis of existing educational television (ETV) stations and the networking, also on a national basis, of accredited medical schools. The first provides the cost of one-time (occasional) broadcasts aimed primarily at the biomedical community. The second provides the networking cost of a national closed circuit TV network for the nation's medical schools.

The ETV network was defined to include only ETV stations with at least one Standard Metropolitan Statistical Area (SMSA) within broadcast range to assure a sufficiently large audience. Also, data on physician population by SMSA are available, which makes it possible to calculate some measure of potential audience size.

With the data available, it was found that approximately 96.7 percent of the SMSA physician population could be reached by 106 ETV stations. Further, it was found that because there was a very uneven distribution of physicians among these SMSAs, about 90 percent of

this population could be reached by about 49 percent, or 52, of the largest stations.

The networking of the full 106 ETV stations, using the minimum distance network, requires about 12,000 miles of intercity line. The cost per hour is approximately \$80,000 for a 1-hour broadcast and \$27,000 per hour for a 5-hour broadcast. Using an active physician population within range of this network of 260,160 (1970 estimate), the network cost per potential viewer-hour then ranges from 30 cents for the 1-hour broadcast to 11 cents for the 5-hour broadcast.

The second application, the full medical school network, contains 97 schools and requires about 10,000 miles of intercity line at a cost of approximately \$600,000 per month. This network, however, buys about 160 hours of networking time per month and reaches about 85,000 biomedical students. Thus, the networking cost per month per school is approximately \$6000, the networking cost per month per student is \$7, and the networking cost per potential viewer-hour is 5 cents.

These cost figures are predicated on the assumption of a 15-mile average local channel distance and physician population projections described in the text. The sensitivity of the costs to the local channel distance was tested and found not to be very great. The physician population projections are considered reasonably accurate, and since the annual increments in the total population are small relative to the total population, errors in this estimate should have minor impacts.

The cost estimates for the specific configurations described in this study have not been verified with the telephone company, since the purpose of this study is not to determine the precise cost of an in-place system. The purpose is to provide a reasonably accurate assessment of the cost and potential benefit of TV networking as a mode of disseminating information to the biomedical community. These data can also be used for purposes of comparison and planning involving alternative modes of information dissemination.

ACKNOWLE DGMENTS

The authors wish to express their gratitude to D. R. Fulkerson of The Rand Corporation for first suggesting the use of the "minimal weighted spanning tree" algorithm used to calculate the minimal distance networks used in this Memorandum.

I. INTRODUCTION

This Memorandum deals with the problem of land-line, or telephone circuit, networking for the broadcasting of biomedical information. In more specific terms, the Memorandum addresses the problem of finding minimum distance networks for n given points in which a particular point in the network broadcasts to the remaining n-1 points. Such a minimum distance network, utilizing telephone company circuits, will, in turn, be a minimum cost network.

In addition to describing the algorithm for finding the minimum distance network for any n points, two specific applications for networks that might be used to serve the biomedical community are analyzed in detail. The first is networking of the nation's educational television (ETV) stations for occasional, or one-time, broadcasting. The second is the networking of the nation's medical schools for continuous broadcasting.

The first application is intended to indicate both the potential for coverage of the physician population and the networking cost of one-time broadcasts to the medical community using ETV. The second application shows the networking cost of closed circuit TV networks for the nation's medical schools. A second contribution of this analysis is the provision of data and methodology for examining costs and effectiveness (measured in terms of physicians and students within broadcast range) of configurations of subsets of points in the full network.

It is important to emphasize that the data and methodology could also be used for determining the minimum cost for networks using media other than broadband television broadcasting. For example, one might use such networks for broadcasting audio only, in conjunction with slides or still pictures. Finally, the cost attractiveness of networked, simultaneous broadcasting can be compared with, for example, sequential broadcasting using mailed video tapes.

In what follows, there is first a brief description of the methodology used to determine the minimum distance network for each set of points considered. Then the specific cities for the ETV networks

are described. This is followed by a description of the AT&T rates for networking, cost estimates for the networks, and a brief discussion of the cost. The procedure is then repeated for the medical school networks.

II. MINIMUM DISTANCE NETWORK CONFIGURATIONS

Most communication-system-design problems are more difficult to solve than the broadcast network problem addressed here. For example, in a message-switching communication system, line loads must be balanced and response times through queues calculated. In the broadcast network problem, it is possible to take advantage of the homogeneity of the network traffic and to define it as a problem capable of strict optimization. The broadcast network is an inherently efficient way to "use" lines; the broadcast message utilizes all the capacity of all lines without overloading any line and there are no illegal concentrations or unbalancings. Thus, the optimizing problem is simply one of minimizing the total line miles. This minimum distance network is, in turn, a minimum cost network.

A minimum distance network over n points is a "tree." A tree is a connected graph that has no circuits. This means that there are no multiple edges and that there is only one path connecting any pair of points. A tree over n points has n-1 edges. If we were to draw a network with more than n-1 edges, then multiple paths must exist between some points and the network would not be optimal.

Now, there is not just one tree over n points. There are, in fact, n^{n-2} different trees. This is unwieldy for large n. For example, the number of trees for 100 points is 10^{196} [= $(10^2)^{98}$]. Thus, bruteforce enumeration and trial of these trees would be out of the question. Fortunately, there is a theorem that guarantees that it is possible to find a minimum distance tree in fewer tries. This theorem provides us with a simple "economy rule": We begin with the least expensive link, forming a tree over two of the points. Thereafter, we add the least expensive link between a point in the tree and a point outside the tree. After repeating this process until n-1 links have been drawn we are assured that we have drawn a minimum distance tree. During this process, (k)(n-k) comparisons must be made when k points

^{*0.} Ore, Graphs and Their Uses, Random House, New York, 1963, pp. 38-40.

are already connected, so a total of

$$\sum_{k=1}^{n-1} k(n-k) \int_{1}^{n-1} k(n-k) dk = \left(\frac{n^{3}}{6} - n\right)$$

trials are needed to solve the problem using this technique. This is approximately 166,000 (1.66 \times 10^5) trials for 100 points, considerably fewer than a comparison of all possible trees.

The general name given to the type of tree we are using in this paper for the network configurations is a "minimal weighted spanning tree." In this application the weights used are the distances in airline miles between the points included in the tree. The JOSS † program used for the calculations is shown in Appendix A. This program calculates the distances between any two cities i and j from the vertical (V) and horizontal (H) coordinates of each city using the following formula:

$$\sqrt{\frac{(v_i - v_j)^2 + (H_i - H_j)^2}{10}}$$

The coordinates used in this formula (see Tables 1 and 2) are not the standard geographical coordinates of the cities but, rather, the coordinates of points in a plane onto which the points on the earth's spherical surface have been transformed. For this reason, the above formula, which disregards the curvature of the earth's surface, can be used. The number 10 in the denominator is simply an arbitrary scaling factor used in the transformation. With these V and H coordinates and

JOSS is the trademark and service mark of The Rand Corporation for its computer programs and services using that program.

Note that this is different from the "traveling salesman problem" of forming the minimal path (line series) through n points. Although there are fewer paths than trees, namely (n-1) factorial, no completely satisfactory computational method has been developed to find the optimal path. For example, for 100 points there are 9×10^{153} paths and a very substantial number of these must be inspected to approach optimality.

the above formula, the official airline distance between cities approved by the FCC for applying telephone company rates can be obtained with the JOSS Program in Appendix A for any given set of cities.

III. ETV NETWORKING

As of December 31, 1966, there were 272,891 non-Federal (those not employed by the Federal Government) physicians in the United States (including Hawaii and Alaska) and its possessions. Of these, 230,518, or 84.5 percent, were located in the 300 Standard Metropolitan Statistical Areas (SMSAs) in the U.S. Since data on the distribution of physicians at the city level are available only for physicians in SMSAs and since such a large percentage of the total physician population appears to reside in these areas, the ETV network described here is restricted to only those stations that reach at least one SMSA.

By the end of 1969, there were 183 ETV stations in the U.S., excluding Alaska and Hawaii. Of these, 45 stations in five separate states are included in statewide ETV networks. Each statewide network can be included in the larger network by a single connection.

Thus, all 183 stations can be reached by connecting 143 of the stations. Further, 17 of the stations are in eight cities with more than one ETV station to that the total area that could be reached by ETV can be reached by connecting only 134 stations. Of the 134 distinct stations that would be candidates for inclusion in a full nationwide ETV network, 106, or 79 percent, of the stations are in or around SMSAs.

These 106 ETV stations reach 96.7 percent of all non-Federal physicians listed as being in SMSAs.

^{**}New York City has 3 stations; Miami, Chicago, Boston, Minn-eapolis-St. Paul, Pittsburgh, Richmond, and Milwaukee have 2 each.

Distribution of Physicians, Hospitals and Hospital Beds in the U.S., Vol. 2, Metropolitan Areas, American Medical Association, Chicago, 1966.

Tbid. The list of 300 also includes what are called "potential" SMSAs. This definition of the SMSAs is that of Sales Management, Inc., rather than the U.S. Office of Statistical Standards.

^{*1969} Directory and Yearhook of Educational Broadcasting, National Association of Educational Broadcasters, Washington, D.C., 1969.

The state networks are Alabama, 8 stations; Georgia, 10 stations; Kentucky, 13 stations; South Carolina, 5 stations; and Nebraska, 9 stations.

Two steps were taken to determine the number of SMSAs reached by each TV station and the potential physician audience at each of these stations. First, a complete list of SMSAs, by state, with the number of non-Federal physicians in each SMSA was compiled. Next, the location of all ETV stations in the U.S. was determined and the following rule applied: All SMSAs within 50 miles of a UHF ETV station, or within 75 miles of a VHF station, were counted as being in the broadcast range of that station.

This rule is somewhat arbitrary since the radius of range is not generally constant for any given station or the same among stations. However, the rule is adequate for the purposes of this study since total cost is not affected by these figures and accurate data for the distribution of the potential physician audience are available only for SMSAs. This latter fact limits the usefulness of a more accurate analysis of the actual radius of each station. The rule of 50 and 75 miles is, perhaps, a bit generous, but this should offset the fact that there are undoubtedly some physicians within the broadcast range of some of the ETV stations who do not reside in SMSAs and, thus, have not been counted in the SMSAs' population total.

The complete list of locations of the 106 ETV stations with their V and H coordinates, is shown in Table 1, together with the rank of that station measured in terms of the number of non-Federal physicians residing within broadcast range. A full listing of all the SMSAs in the range of each station, the physician population within SMSAs, and the total number of physicians per ETV station is shown in Appendix B. The cumulative frequency distribution of this population plotted against the ETV stations in descending order of rank is shown in Fig. 1. It is important to note that this is the cumulative distribution of the total physicians reached (230,518), not the total non-Federal physician population (272,891).

Using the V and H coordinates in Table 1 and the JOSS program in Appendix A, the minimum distance networks for all 106 stations and the largest (lowest rank) 5, 10, 15, 20, and 52 ETV stations were calculated. The results of these calculations provide the total miles for each set of stations, the total population reached, and the percentage of the total within reach as shown in Table 2.

20	5,981	146,232	65.4
52	8,397	200,620	89.7
106	12,031	223,583	100.0

^aIncludes only miles from program operating center o program operating center in each city.

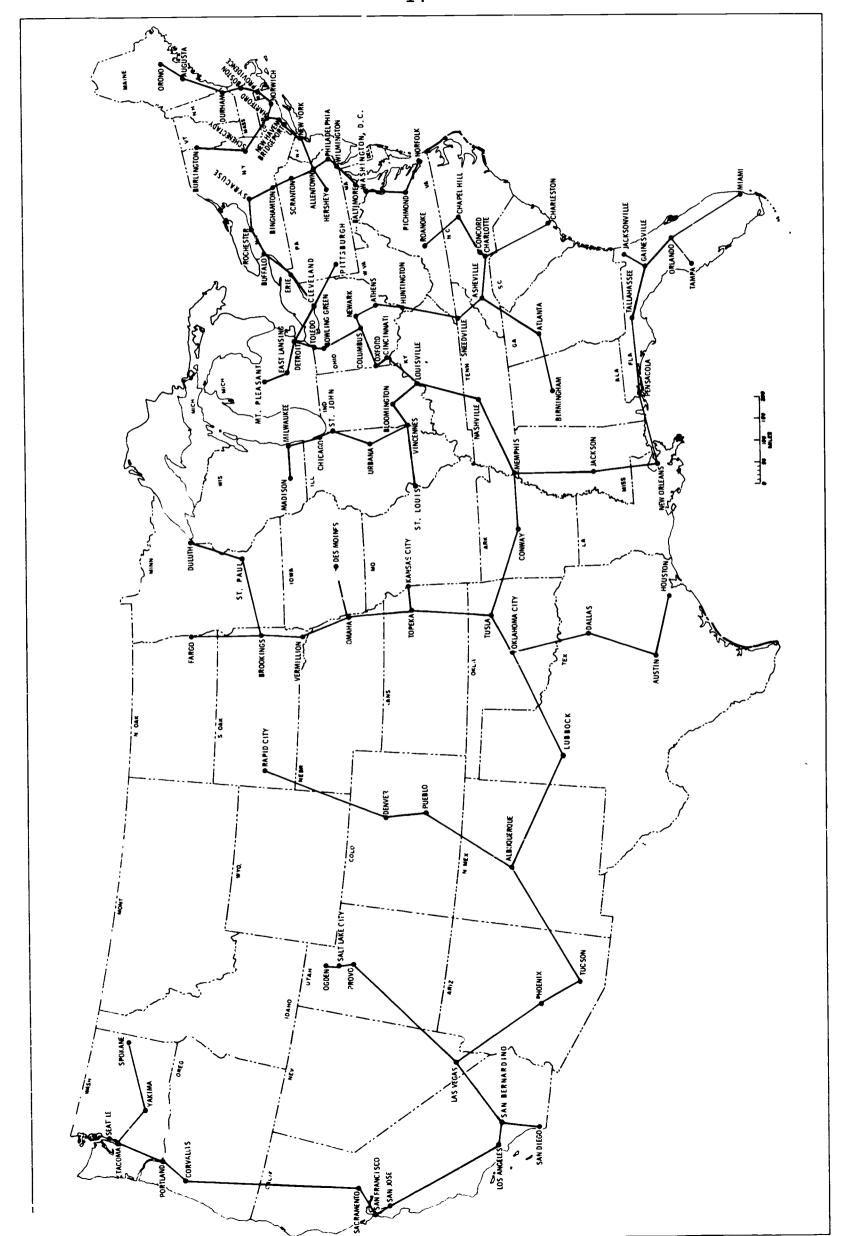

The printouts of these runs showing the links in each network, the intermediate numbers of miles and physicians reached, and miles per physician reached are in Appendix D. A map of the full 106-city network is shown in Fig. 2.

The stations were stored in the computer in descending order of audience size. Thus, networks for the N largest population centers can be calculated by truncating the list after N. Any N solution obtained represents the least expensive way to network the full audience in that particular subset of cities. The subset selected, however, is not necessarily that which gives the absolute minimum cost for a given audience size. Finding such a subset poses an entirely different analytical problem. In addition, such a result might omit logically important cities or regions.

The map does not show networks in the following states: Alaska, Montana, Wyoming, New Jersey, Idaho, and Hawaii. The first three, Alaska, Montana, and Wyoming, have no ETV stations. New Jersey has no ETV station, but its cities are served by stations in New York City and Philadelphia. Idaho has an ETV station at Moscow, but there is no SMSA or medical school within the broadcast range. Hawaii has a

based on the 1966 non-Federal physician population in SMSAs.

ERIC Full fast Provided by ERIC

Fig. 2--Minimum distance ETV network of 106 stations

statewide ETV network; however, it can only be connected by satellite via San Francisco and falls outside the basic network problem. In addition, the rates to Hawaii are different from the Continental United States rates: The interexchange rates are \$550 for the first 10 minutes and \$16 per minute for each additional minute. This is equivalent to a rate of \$1350 for the first hour and \$960 for each additional hour. This link could be optionally included in any network serving San Francisco.

IV. ETV NETWORKING COST

Using the total intercity mileages shown on page 13, the networking costs for each of the network sizes can be estimated. * TV networking costs, utilizing the facilities and services of AT&T, have three separate components: (1) interexchange channel charges based on airline distances between cities; (2) station connecting charges for each TV station; and (3) local channel charges for connecting the TV station to the local AT&T program operating center.

Further, the rates for each of these components are given separately for the video (black and white) signal and the audio; and the audio comes in two grades of service: the 100- to 5000-cycle frequency, and the 200- to 3000-cycle frequency. Finally, the rates differ for occasional use and continuous use. For the ETV network, the following occasional-use rates will be used:

- One way, black and white video signal (occasional use):
 - 1. Interexchange channel rate: \$1 per mile per hour.
 - 2. Station connection charge (per station): \$200 for each occasion used plus \$10 per hour for each hour of use.
 - 3. Local channel rate (per station): \$175 per month plus

 15 percent of the rate for continuous service for the

 first 24 hours plus 10 percent of the same for each

 additional 24 hours in the same month.
- One way audio, 100- to 5000-cycle frequency service (occasional use):
 - 1. Interexchange channel rate: \$0.15 per mile per hour

for all audio cases the rates vary from location to location, but those given are representative.

These costs exclude the broadcasting cost and the cost of the production of the material to be broadcast.

All rates cited were obtained verbally by phone from Mr. D. Brinton in the Los Angeles office of AT&T on August 20, 1969.

^{*}No occasion may exceed 24 hours.

^{**}The continuous service rates are given on p. 28 for the medical school network.

plus \$0.0375 per mile for each consecutive 15-minute period. Minimum charge: \$2.00. Maximum charge: the continuous service rate.*

- 2. Station connection charge (per station): \$20 per month plus \$1.75 per hour.
- 3. Local channel rate (per station): \$15 per month plus \$3.45 per mile for the first week plus \$6.90 per mile per week after the first week.
- One way audio, 200- to 3000-cycle frequency service (occasional use):
 - 1. Interexchange channel rate: \$0.10 per mile for the first hour plus \$0.025 per mile for each additional 15 minutes on each occasion. Minimum charge: \$1.50 per mile. Maximum charge: \$4.50 per mile.
 - 2. Station connection charge (per station): \$6.25 per mile. Minimum charge: \$10. Maximum charge: \$20.
 - 3. Local channel (per station): \$2.95 per mile for the first week plus \$5.90 per mile per week for periods greater than one week.

In estimating the network costs, two major simplifying assumptions were made. First, it was assumed that the average local distance from the program operating center to the ETV station in each city was 15 miles and, second, that the 100- to 5000-cycle frequency audio service would be used throughout the network. This latter assumption is conservative since some of the shorter links in each network might be able to use the less expensive 200- to 3000-cycle service.

The total one-time networking cost for various network sizes for 1, 2, 3, 4, and 5 hours of one-way video and audio broadcasting is shown in Table 3. The costs for average local distances ranging from 5 to 25 miles are shown in Appendix D, together with the average costs per mile and the average cost per hour. The JOSS program used to calculate these costs is also included in this appendix.

^{*}The continuous service rates are given on p. 28 for the medical school network.

Table 3

TOTAL COST FOR ONE-TIME NETWORKING
(\$)

Number of	Broadcast Hours					
ETV Stations	Z	2	3	4	5	
5	6,106	9,240	12,374	15,508	18,642	
10	10,267	14,589	18,911	23,233	27,555	
15	14,355	19,793	25,230	30,668	36,105	
20	19,003	26,116	33,229	40,343	47,456	
52	41,182	51,449	61,717	71,984	82,252	
106	78,098	93,179	108,260	123,342	138,423	

Besides providing networking costs for the various size networks shown, these costs also point out the uneven distribution of the physician population indicated in Fig. 1. About 90 percent of the physicians within reach of the 106-ETV-station network can be reached by the 52 largest stations. This smaller network costs approximately half the 106-station network. Thus, this network, reaching a large subset of the physicians, is considerably more cost effective than total coverage, even though we have not solved for the absolute minimum way of reaching any subset of the total population.

A second interesting fact about the 106-ETV-station network illustrated in Fig. 2 is that there is no apparent significant cost saving method for regionalizing the minimum cost national network. Removal of the links between, say, Albuquerque and Lubbock, and Tulsa and Conway, would create three regions with virtually no east-west overlap. The savings, however, would amount to only \$600, approximately, in total cost for each hour of broadcast (i.e., interchannel charges per mile per hour times the distances between each pair of cities). The reason for the limited cost saving opportunities from regionalization stems from the fact that there are no "clusters" or groups of cities connected from one central city in the minimum cost network. Thus, this analysis of minimum cost networks for ETV stations gives no direct indication of how one might logically regionalize the nation for communication purposes. It does, however, highlight the fact that there are large cost savings to be derived from not attempting

to attain 100 percent coverage, given the uneven distribution of the physician population.

Looking next at the cost per hour per physician (i.e., cost per potential viewer-hour) within broadcast coverage area, based on the 1966 non-Federal physician population and the 106-station network, the cost is approximately 35 cents per potential viewer-hour for 1 hour of networking and approximately 12 cents for 5 hours.

Extrapolating total physician population in the Continental **
United States (including osteopaths) to 1970 ** and assuming that the percentage of this total reached is the same as the percentage of the total 1966 non-Federal physician population reached (81.7 percent), the potential viewer population, based on all active physicians, increases from 223,583 to 260,160. In this case, the networking cost per potential viewer-hour ranges from 30 to 11 cents.

If one further assumes an average broadcast cost of \$175 per hour per station, total network broadcasting cost, excluding content preparation and production, for the 106-station network becomes \$96,648 for 1 hour and \$231,173 for 5 hours. This results in a cost per potential viewer-hour of 37 cents for 1 hour and 18 cents for 5 hours. Moving to the 52-station network, the unit cost per potential viewer-hour, including both networking and broadcasting, reduces to 22 cents for 1 hour and 11 cents for 5 hours.

The above costs are predicated on an assumed 15-mile average local distance. A comparison of cost per potential viewer-hour for other average distances is shown in Table 4 for both the 106- and the 52-station networks. These results demonstrate that the cost per potential viewer-hour changes only 10 percent at most for a 10-mile change in average local distance.

The fact that this assumption does not significantly alter the results is important, since it indicates that minor variations in telephone company practice with respect to local channel connections would not drastically alter the results. The importance of this stems

J. A. Dei Rossi, et al, A Telephone Access Biomedical Information Center, The Rand Corporation, RM-6205-NLM, forthcoming, Winter 1970.

Table 4

NETWORK AND BROADCAST COST PER POTENTIAL VIEWER-HOUR
(\$)

		our of adcasting	5 Hours of Broadcasting	
Local Channel Distance (mi)	106 Stations	52 Stations	106 Stations	52 Stations
5	.33	.19	.17	.10
10	.35	.21	.18	.11
15	.37	: 22	.18	.11
20	.39	.23	.18	.11
25	.41	.23	.18	.11

from the fact that these results have been calculated without verification by the telephone company of any of the specific configurations. Such verification was not sought because the purpose of this study is not to determine the precise cost of an in-place system, but rather to provide a reasonable assessment of the economic cost and potential benefit of ETV networking for the biomedical community. This provides a basis for planning and comparison with other means of information dissemination.

V. NETWORKING MEDICAL SCHOOLS

There are currently 97 accredited medical schools operating in the United States (excluding Hawaii and Puerto Rico).* However, some of the medical schools are located in the same cities and could be served by the same program operating centers; the 97 schools can be served by 72 program operating centers (POCs). A list of these POCs, ranked from largest to smallest potential population, together with the V and H coordinates for each is shown in Table 5. A full listing of the schools served by each of these centers and the total potential population reached by each is included in Appendix E. The cumulative frequency distribution of this population is plotted against the POCs in descending order of rank in Fig. 3.

Using the V and H coordinates for the POCs and the JOSS program in Appendix A, the minimum distance networks for all 72 POCs and for the largest (lowest rank) 5, 10, 15, 20 and 48 centers were calculated. The results of these calculations showing the total miles for each of the networks, the total population reached, and the percentage of the total are as follows:

Number of POCs	Number of Schools	Total Miles	Student Popu- lation Reached	Percent of Total Population
5	23	2,674	23,274	27.4
10	31	3,751	3. √ ,146	40.2
15	38	4,823	43,333	51.1
20	43	5,608	50,470	59.5
48	73	7,965	76,609	90.3
72	97	9,966	84,857	100.0

The printouts of these runs showing the links in each network, the intermediate numbers of miles, and student population reached is shown in Appendix F. A full map of the 72 program operating center

The Journal of the American Medical Association, Vol. 206, No. 9, List 92, Nov. 25, 1968. Five new schools have been added: the University of California at Davis, the University of California at San Diego, the University of Connecticut, Mt. Sinai in New York, and the University of Texas at San Antonio.

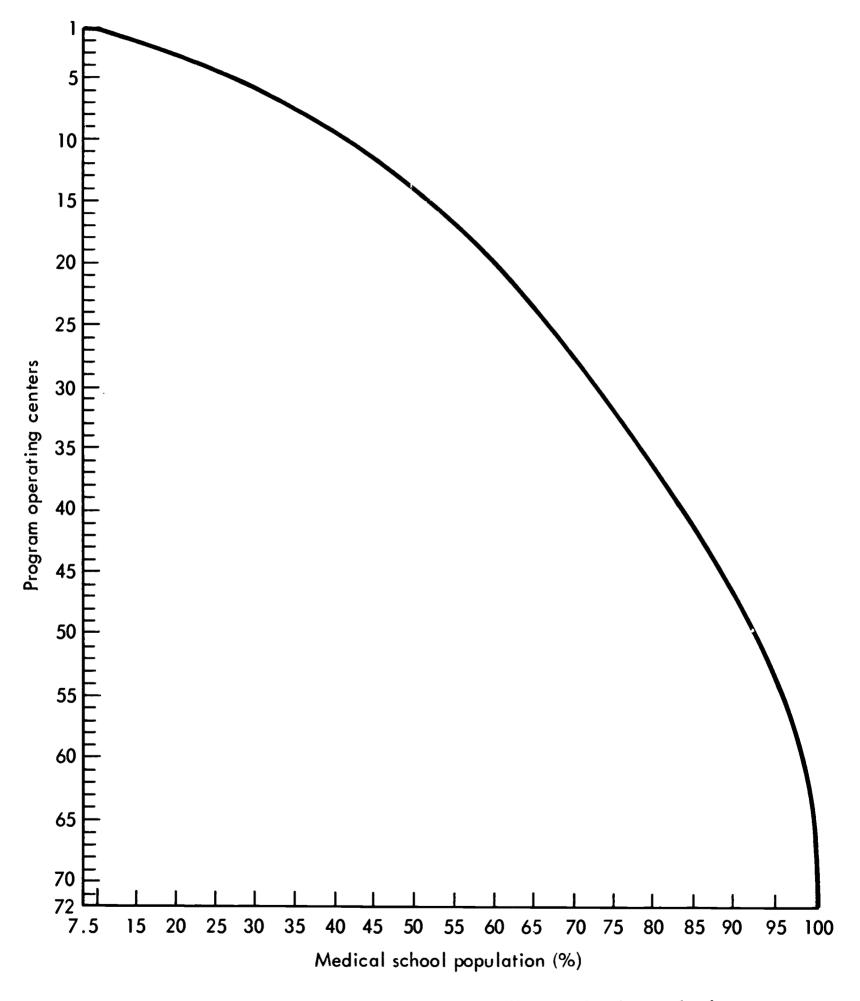

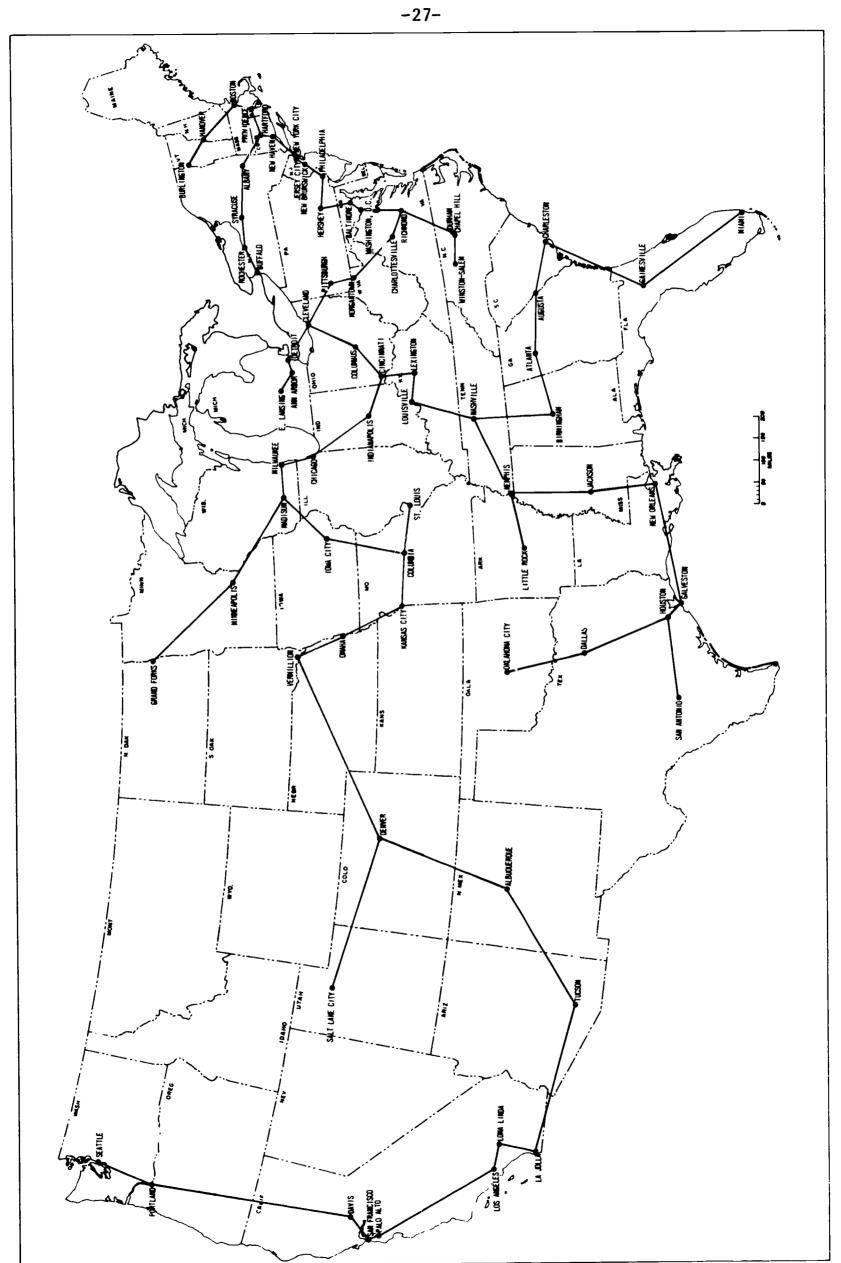

Fig. 3--Cumulative distribution of medical school population reached by 72 program operating centers

network is shown in Fig. 4. As with the ETV case, the subset of cities selected will not necessarily give the absolute minimum cost for a given audience size.

VI. MEDICAL SCHOOL NETWORKING COST

The same components of cost that applied to the costs of the ETV network apply to the medical school network. However, for the medical schools, the telephone company contract service (continuous-use) rates will be used. The contract service rates are monthly rates for everyday use for the stipulated number of hours per day. These rates are as follows:

- One way, black and white video signal (continuous use):
 - 1. Interexchange channel rate (per month): \$35 per mile for an 8-hour block of time plus \$2 per mile for each additional continuous hour up to 2 hours plus \$.25 per hour for each additional continuous hour on each occasion when more than 10 hours are used.
 - 2. Station connection charge (per station per month): \$500 plus \$35 per hour for the first 10 hours plus \$5 an hour for each additional consecutive hour on each occasion when more than 10 hours are used.
 - 3. Local channel rates (per station per month): \$175 plus \$20 per quarter mile for the first 8 miles plus \$35 per mile for miles in excess of 8.
- One way audio, 100- to 5000-cycle frequency service (continuous use):
 - 1. Interexchange channel rates (per month): \$4.50 per mile for an 8-hour block of time plus \$.25 per mile for the next continuous 3 hours plus \$.15 per mile for the next 5 continuous hours.
 - 2. Station connection charge (per station per month): \$55 for the first 8-hour block of time plus \$3 for the next 3 continuous hours plus \$2 for each additional hour.
 - 3. Local channel rate (per station per month): \$15 plus \$6.90 per mile.

As with the ETV case, these costs exclude the station broadcasting cost and the cost of production. In addition, for this case, the costs of constructing facilities for receiving and transmitting at each of the medical schools is also omitted.

- One way audio, 200- to 3000-cycle frequency service (continuous use):
 - 1. Interexchange channel rate (per month): \$1.50 per mile for the first hour plus \$.25 for each additional consecutive hour. Maximum charge: \$4 per mile.
 - 2. Station connection charge (per station per month): \$15 for the first hour plus \$1.50 for each additional hour.

 Maximum charge: \$20.
 - 3. Local channel rate (per month): \$5.90 per mile.

In estimating the medical school network cost, the same two major assumptions used for the ETV network were made: 1) that the average local channel distance was 15 miles, and 2) that the 100- to 5000-cycle frequency audio service would be used throughout the network.

There are a number of fixed costs (i.e., costs not sensitive to the number of broadcast hours) and the interexchange channel rates buy 8-hour blocks of time, so that the total monthly networking cost difference between utilizing the network 1 hour per day and 8 hours per day is quite minimal, averaging less than 4 percent. Further, given the fact that this network would require extensive investment cost in broadcasting and receiving equipment, one would expect it to be used extensively, if at all. Therefore, only the cost of 8 hours per day of continuous broadcast networking will be described.

The following figures show the total monthly networking cost for 8 hours per day for the various size networks discussed in the preceding section, assuming an average local distance of 15 miles: The costs for average local distances ranging from 5 to 25 miles, the average monthly cost per school, and the average monthly cost per student are

Number of	${\it Cost}$
Schools	(\$)
23	151,934
31	210,583
38	267,022
43	308,097
73	461,603
97	588,967

given in Appendix G. The JOSS program used to calculate these costs is also in this appendix.

As with ETV networking, these costs highlight the uneven distribution of the population shown in Fig. 3. However, in this case, the total cost saving in reaching 90 percent of the population, as opposed to 100 percent, is not as great. Approximately 90 percent of the population at the 73 largest schools (48 POCs) can be reached at a cost saving of 22 percent.

Another interesting feature of these results relates to unit costs: Total monthly cost per school and cost per student are highly insensitive to network size. The following are the average monthly continuous-networking costs per school for each size network for 8 hours per day:

Number of	${\it Cost}$
Schools	(\$)
23	6606
31	6793
38	7027
43	7165
73	6323
97	6072

From these figures, it can be seen that the average cost per school varies only by approximately 15 percent from the largest to the smallest network.

The following are the average monthly continuous-networking costs per student for 8 hours per day:

Number of Schools	Cost (\$)
23,274	6.53
34,146	6.17
43,333	
50,470	
76,609	
84,857	

These costs show essentially the same insensitivity of cost per student to network size.

If one assumes that there are an average of 20 school days per month, 8 hours per day of continuous networking provides 160 hours

per month of broadcast networking. Using this figure, the network cost per potential viewer-hour is less than 5 cents for every size network and varies at most, by 10 percent for a 10-mile change in local channel distance. These cost figures, like those for the ETV network, have not been verified with the telephone company for any of the specific configurations. They are intended for planning and comparison purposes only.

Appendix D

JOSS PROGRAM AND PRINTOUTS OF COST FOR VARIOUS ETV NETWORK SIZES

This Appendix contains the JOSS program for estimating ETV networking cost and the printouts of the cost estimates for various network sizes. The program demands as inputs:

M as the miles of interchange channel.

N as number of ETV stations.

Using these inputs and the rates described in Section IV, the following variables are calculated for 1, 2, 3, 4, and 5 hours of broadcasting, and 5, 10, 15, 20, and 25 miles of local channel service.

B as video station connection cost.

G as audio station connection cost.

A as video interchange channel cost.

F as audio interchange channel cost.

D as video local channel cost.

E as audio local channel cost.

 $\mathtt{C}(i,j,1)$ as total cost for i hours and j local channel miles.

 $\mathtt{C}(i,j,2)$ as cost per mile for i hours and j local channel miles.

C(i,j,3) as cost per hour for i hours and j local channel miles.

JOSS PROGRAM FOR CALCULATING ETV NETWORKING COST

1.01 Page.

		Medical School Population ^a		
Rank	Medical Schools Served by Each POC	Per School	Per POC	
72	Tucson, Ariz. University of Arizona	32	32	

^aTotal Medical Population includes Medical Students; Interns; Residents; Masters, Basic Science; Doctoral, Basic Science; Postdoctoral, Basic Science; Clinical Fellows, Postdoctoral; and Medical Student equivalents in the areas of Dentistry, Pharmacy, Nursing, and other paramedicines.

brown these schools enrollment figures were available for medical students only and not for total population as defined above. In these cases, total population was derived by multiplying by the ratio of the average number of medical students to total population (medical) for the 92 schools for which both figures were available. That ratio was found to be 1:2.455.

Appendix G

JOSS PROGRAM AND PRINTOUTS OF COSTS FOR VARIOUS SIZE MEDICAL SCHOOL NETWORKS

This Appendix contains the JOSS program for estimating Medical School networking cost and the printouts of the cost estimates for various network sizes. The program demands:

- M as the miles of interchange channels.
- N as the number of medical schools.
- Z as the number of months.
- Y as the number of medical students.

Using these inputs and the rates described in Section VI, the following variables are calculated for 1, 2, 4, 6, and 8 hours of broadcasting, and 5, 10, 15, 20, and 25 miles of local channel

- B as video station connection cost.
- G as audio station connection cost.
- A as video interchange channel cost.
- E as audio interchange channel cost.
- D as video local channel cost.
- E as audio local channel cost.
- C(1,j,n) as total cost for n schools and
 - j local channel miles.
- C(2,j,n) as cost per school for n schools and
 - j local channel miles.
- $\mathcal{C}(3,j,n)$ as cost per student for n schools and
 - j local channel miles.
